(Dated: 13 November 2019)

The Complete Active Space Second-order Perturbation Theory (CASPT2) has been one of the most widely used methods for calculating the electronic structure of the multireference systems with semi-quantitative accuracy. As a simple, yet higher-order approach, we have developed a hybrid theory of the CASPT2 and a multireference variant of the Coupled-Electron Pair Approximation (CEPA) in the fully-internally contracted (FIC) framework. In the newly developed theory (CEPT2), the external components of the wave functions, which usually give the most significant contribution to the dynamic correlation energy, are solved at the CEPA level while the rests are treated at the CASPT2 level. Moreover, using an automatic expression and code generation technique, we have implemented the CASPT2 and CEPT2 approaches in the pair-natural orbital (PNO) framework to reduce their computational costs with respect to the number of atomic orbital (AO) basis. To highlight the accuracy of the CEPT2 approach and to assess the errors caused by the PNO truncation, we have performed benchmark calculations on small- to medium-size molecules including dissociation of N₂ molecule, the singlet-triplet splitting of the free-base porphyrin molecule. We demonstrate that by tightening the truncation thresholds the PNO-CEPT2 energy converges toward the canonical counterpart and that the PNO-CEPT2 results are more accurate than that of PNO-CASPT2 as long as the same truncation thresholds are used.

I. INTRODUCTION

Electronic structures that cannot be well approximated by a single Slater determinant are common in chemistry. Electronic wave function of the low-spin open-shell states where there are multiple anti-ferromagnetically coupled electrons is a very typical example of such cases.¹ The electron correlation effect that plays an important role in these problems is often referred to as static correlation.² However, to obtain quantitative accuracy, it is often necessary to consider dynamic correlation which is the remaining component of the correlation effect. The most straightforward way to take into account both types of correlation in a well-balanced manner is the multireference (MR) wave function theories^{3,4} that are based on the multiconfigurational self-consistent field (CASSCF) reference function.⁵⁻⁷ Note that there are tremendous attempts to utilize the single-reference (SR) framework⁸⁻¹⁷ for capturing the static correlation effect.

Amongst the MR wave function theories, the Second-order Complete-Active-Space Perturbation Theory (CASPT2) pioneered by Roos and coworkers^{18,19} in early 90s have been used as a fundamental tool for achieving quantitative accuracy for systems of complicated electronic structure including organic molecules of doubly-excited nature²⁰ and mono-^{21,22} and multinuclear^{23,24} transition metal complexes. A newer variant of CASPT called N-Electron Valence-state Perturbation Theory (NEVPT) was proposed by Angeli *et al.*²⁵⁻²⁷ using Dyal’s zeroth-order Hamiltonian²⁸ to overcome some of the shortcomings of CASPT approach. As both approaches converge to the conventional second-order Møller-Plesset (MP2) perturbation theory²⁹ in the closed-shell SR limit, floating-point operations (FPOs) needed to calculate CASPT2 and NEVPT2 energies scale at least as $O(c^2v^2)$ for system with a fixed number of active molecular orbitals (MOs) where c and v represent the number of doubly-occupied and virtual MOs, respectively. Before calculating CASPT2 energy, one has to solve the first-order amplitude equations and hence the memory or storage requirement scales also as $O(c^2v^2)$. For a system with more active MOs, the prefactors of both memory and FPO requirements steeply increase because their working equations involve the reduced-density matrices (RDMs) of up to four-body nature. Therefore, routine application of CASPT2 methods to systems with more than 1,000 atomic orbital (AO) functions often becomes prohibitively expensive.

To improve the applicability of CASPT2 approach, numerous efforts have been made including use of frozen-natural orbitals (FNOs)^{30,31} in the virtual space in conjunction with the Cholesky decomposition technique for reducing the costs of MO integral transformation³²⁻³⁵ and of the tensor-

hyper-contraction-based (THC-) CASPT2.³⁶ The density-fitting (DF) or resolution-of-the-identity (RI) approximation has also been used for accelerating CASPT2 computation.³⁷ Recently, Katz and Werner developed a CASPT2 approach in the so-called pair-natural orbital (PNO) framework, which has been coined PNO-CASPT2, and demonstrated its applicability to large, real-life MR systems composed of up to approximately 3,000 AO functions.^{38,39}

The original concept of PNOs was already realized in 60s in order to accelerate the convergence of the configuration interaction (CI) expansions.⁴⁰⁻⁴⁶ Importantly, the PNO-based MRCI theory and the MR Coupled-Electron Pair Approximation (PNO-MCCEPA) using internally-contracted (IC) configuration functions were developed by Taylor⁴⁷ and Staemmler *et al.*,⁴⁸ respectively.

The use of PNOs in the context of modern wave function theories was first introduced by Neese and coworkers in their local PNO-based (LPNO-) CEPA⁴⁹ and Coupled-Cluster (LPNO-CC)⁵⁰⁻⁵² methods implemented in Orca package.⁵³ The LPNO-CEPA/CCSD is applicable to systems composed of up to 2,000 AO basis which is far beyond the reach of canonical counterpart while recovering almost 99.9 % of the canonical correlation energy. Later they have developed a more sophisticated variant called domain-based LPNO-CC (DLPNO-CC) methods for large, real-life systems involving hundreds of atoms and thousands of AO functions.⁵⁴⁻⁵⁹ The DLPNO scheme has been extended to MR wave function theories resulting in DLPNO-Mk-MRCCSD⁶⁰⁻⁶² and DLPNO-NEVPT2⁶³ methods. In a similar vein, variants of PNO-based reduced-scaling wave function methods have been developed by many research groups including PNO-LCC methods by Werner *et al.*⁶⁴⁻⁷⁰ and a variant of PNO-CC method and PNO-based theories for the excited states by Hättig *et al.*⁷¹⁻⁷⁹ to only name a few.

In this paper, we report a hybrid of IC-MR-CEPA and CASPT2, which is coined CEPT2, as a higher-order, yet simple extension to the conventional CASPT2 method for capturing more dynamic correlation. The 2-external configurations in the first-order CEPT wave function are treated at the IC-MR-CEPA level while the remaining semi-internal and the internal configurations are kept at the CASPT2 level. The coupling between two Ansätze has been accomplished in a similar vein to the CIPT2 model by Werner and co-workers⁸⁰. In the closed-shell SR limit, the CEPT2 model converges to the linearized coupled-cluster doubles (L-CCD) or equivalently the CEPA/0 doubles (CEPA/0(D)) that recovers more dynamic correlation energy than the MP2 model. Note that Fink and co-workers proposed a variant of MR perturbation theory⁸¹⁻⁸³ that also converges to the L-CCD or CEPA/0(D) model in the closed-shell SR limit at the second-order level and is known as the so-called Retention of Excitation degree Perturbation Theory (REPT).

In the original CIPT2 model,^{84,85} the reference configurations, $(active, active) \rightarrow (active, virtual)$ and $(active, active) \rightarrow (virtual, virtual)$ excited configurations are treated at the MRCI level while leaving the remaining ones at the CASPT2 level in order to remedy the intruder state problem without employing the real⁸⁶ and imaginary⁸⁷ shifts. Actually, treating those configurations with three active MO indices in the IC framework at the MRCI level is known to cause several computational difficulties the most severe one of which is the appearance of 5-RDMs.⁸⁸ An active space 5-RDM is a tensor quantity associated with 10 active MO indices and hence for those systems with 16 active MOs generation and storage of the 5-RDM require more than 8.0 terabytes of disk space. Therefore, in the partially IC-MRCI models^{85,89} implemented in Molpro package, such configurations are uncontracted to remove them from the working equations.

Later, by rewriting the Hamiltonian matrix element into a commutator-based expression as done in the NEVPT2 formulation,²⁵ the MRCI theory in a fully IC framework (FIC-MRCI) without 5-RDM was formulated.⁹⁰⁻⁹³ However, tensor contractions involving the 4-RDM and the amplitude in the FIC-MRCI σ -equation can still be a bottleneck even for systems with relatively small active space as their computational scaling is either of $O(ca^8)$ or $O(a^8v)$ with a being the number of active MOs. In the CEPT2 model, on the other hand, such contractions do not appear in the residua and all the 4-RDMs are contracted to the Fock operator thus appearing as an effective 3-body tensor with $O(a^8)$ costs just as in case of CASPT2.

Even though the full IC-MR-CEPA/0 lacks size-consistency, all the CEPA terms introduced are fully-connected and thus the near-size-consistent nature of CASPT2 is directly inherited to the CEPT2 model. Use of MR-CEPA ansatz for the 2-external subspaces introduces several terms involving 4-external MO integrals contracted to the amplitude, which may potentially make the whole computation quite demanding even for relatively small systems. This type of contraction terms are often referred to as 4-external exchange operators (4-EEOs) and are known to be the most expensive terms in the SR-CEPA and CCSD computations with $O(c^2v^4)$ computational cost. To overcome this issue, we introduce PNO expansion in the 2-external subspace in a similar vein to Ref. 38. Derivation and implementation of our PNO-CASPT2/CEPT2 scheme have been achieved by an automatic code generation framework which was used in our previous works^{90,91} and has been extended to handle PNOs.

This paper proceeds as follows: In Sec. II, we show how the PNOs are defined in the MR cases and used in the CASPT2 formalism. The PNO-CEPT2 Ansatz is given as a extension to the PNO-CASPT2 model and the strategy we have chosen to use for the automatic code generation

in the PNO framework is addressed. In Sec. III, the accuracy of the canonical CEPT2 model and the PNO truncation errors are validated for N₂ dissociation. The isomerization energy profile calculated at the PNO-CEPT2 level of theory is shown and compared to those by the CASPT2 and the previous theoretical results. The excitation energies (EEs) for the dipole-accessible and dipole-forbidden states of butadiene and longer polyene chains calculated by the PNO-CEPT2 theory are given and compared to the experimental and the theoretical values. Accuracy of the PNO-CEPT2 model are examined by using various PNO truncation thresholds in calculating the Singlet–Triplet energy (S–T) gap for the free-base porphyrin. In Sec. IV finally conclusions are drawn.

II. THEORY

A. Notations and Convention

Throughout this paper, we use $ijkl \dots$, $pqrs \dots$ and $abcd \dots$ to represent the doubly-occupied, active and virtual MOs, respectively, while the generic MOs are indicated by $wxyz \dots$. Derivation and the implementation of the working equations of the PNO-CEPT approach are based on the reduced spin-free excitation operators^{94–97}

$$E_x^w = \sum_{\sigma=\{\alpha,\beta\}} a^{w\sigma} a_{x\sigma} \quad (1)$$

$$E_{yz}^{wx} = \sum_{\sigma,\tau=\{\alpha,\beta\}} a^{w\sigma} a^{x\tau} a_{z\tau} a_{y\sigma} \quad (2)$$

where a^w (a_w) represents the Fermionic creation (annihilation) operator that acts on w -th spatial MO. By using Eqs. (1) and (2), the Born-Oppenheimer Hamiltonian is given as

$$H = \sum_{wx} h_{wx} + \frac{1}{2} \sum_{wxyz} (wy|xz) E_{yz}^{wx} \quad (3)$$

where h_{wx} and $(wy|xz)$ are one- and two-electron integrals. The redundant internally-contracted basis (r-ICBs) that span the first-order interacting space (FOIS) are generated by applying the following eight types of excitation operators to the reference function ($|\Psi_0\rangle$):

$$E_{ij}^{ab}, E_{pi}^{ab}, E_{pq}^{ab} \quad (4)$$

for the external subspaces,

$$\{E_{ip}^{aq}, E_{ip}^{qa}\}, E_{ij}^{pa}, E_{pq}^{ra} \quad (5)$$

the semi-internal subspaces and

$$E_{ij}^{pq}, E_{ip}^{qr} \quad (6)$$

for the internal subspaces. The energy and residual equations involve an expectation value of a string of E -operators with respect to the reference such as $\langle \Psi_0 | E_{ab}^{pq} E_{wx}^{yz} \cdots | \Psi_0 \rangle$. Such an expectation value is evaluated by invoking Wick's theorem for the E -operators and is reduced to a reduced-density matrix (RDM) composed only of active MO indices:

$$D_q^p = \langle \Psi_0 | E_q^p | \Psi_0 \rangle \quad (7)$$

$$D_{rs}^{pq} = \langle \Psi_0 | E_{rs}^{pq} | \Psi_0 \rangle \quad (8)$$

The r-ICBs are non-orthonormal and linearly-independent set of functions as a basis of FOIS. Therefore, the amplitude equations of MR wave function methods are solved in linearly-independent and orthonormalized IC representation spanned by the non-redundant (nr-) ICBs:

$$|\Psi_{ij}^{ab}\rangle, |\Psi_{\rho i}^{ab}\rangle, |\Psi_{\rho}^{ab}\rangle \quad (9)$$

for the external subspaces,

$$|\Psi_{\rho i}^a\rangle, |\Psi_{ij}^{\rho a}\rangle, |\Psi_{\rho}^a\rangle \quad (10)$$

the semi-internal subspaces and

$$|\Psi_{ij}^{\rho}\rangle, |\Psi_{ip}\rangle \quad (11)$$

for the internal subspaces where $\rho\tau\cdots$ are used to represent the eigenvectors of metric for each subspace (Eqs. (4) – (6)).

B. Brief Summary of PNO-CASPT2 Algorithm

As we follow a similar vein to the original formalism by Katz and Werner,^{38,39} we only outline the PNO-CASPT2 theory in this section. In CASPT2 method, the generalized Fock operator is used as the zeroth-order Hamiltonian

$$F = \sum_{wx} f_{wx} E_w^x \quad (12)$$

where f represents the generalized Fock matrix

$$f_{wx} = (f_{\text{core}})_{wx} + \sum_{pq} \left[(wx|pq) - \frac{1}{2}(wp|xq) \right] D_q^p \quad (13)$$

$$(f_{\text{core}})_{wx} = h_{wx} + \sum_i [2(wx|ii) - (wi|xi)]. \quad (14)$$

The PNO-CASPT2 wave function is defined as

$$\begin{aligned} |\Psi\rangle = & \sum_{ij} \sum_{a_{ij}b_{ij}} t_{a_{ij}b_{ij}}^{ij} |\Psi_{ij}^{a_{ij}b_{ij}}\rangle + \sum_{\rho i} \sum_{a_{\rho i}b_{\rho i}} t_{a_{\rho i}b_{\rho i}}^{\rho i} |\Psi_{\rho i}^{a_{\rho i}b_{\rho i}}\rangle \\ & + \sum_{\rho} \sum_{a_{\rho}b_{\rho}} t_{a_{\rho}b_{\rho}}^{\rho} |\Psi_{\rho}^{a_{\rho}b_{\rho}}\rangle + \sum_{\rho ij} \sum_{a_{ij}} t_{a_{ij}\rho}^{ij} |\Psi_{ij}^{\rho a}\rangle + \sum_{\rho i} \sum_a t_a^{\rho i} |\Psi_{\rho i}^a\rangle \\ & + \sum_{\rho} \sum_a t_a^{\rho} |\Psi_{\rho}^a\rangle + \sum_{\rho ij} t_{\rho}^{ij} |\Psi_{ij}^{\rho}\rangle + \sum_{\rho i} t_{\rho}^i |\Psi_i^{\rho}\rangle \end{aligned} \quad (15)$$

in the nr-ICB which is constructed by orthonormalizing and canonicalizing the redundant r-ICBs. For instance, an nr-ICB with double excitations to the active space, $\{\Psi_{ij}^{\rho}\}$, is related to its redundant counterpart as

$$|\Psi_{ij}^{\rho}\rangle = \sum_{pq} C_{pq}^{\rho} |\tilde{\Psi}_{ij}^{pq}\rangle = \sum_{pq} C_{pq}^{\rho} E_{ij}^{pq} |\Psi_0\rangle \quad (16)$$

where the orthonormalization matrix, \mathbf{C} , is obtained by solving the generalized eigenvalue problem:

$$\sum_{rs} \langle \Psi_0 | E_{pq}^{ij} F E_{rs}^{ij} | \Psi_0 \rangle C_{rs}^{\rho} = E_{\rho ij} \sum_{rs} \langle \Psi_0 | E_{pq}^{ij} E_{rs}^{ij} | \Psi_0 \rangle C_{rs}^{\rho}. \quad (17)$$

The PNO-CASPT2 amplitudes are determined by solving the residual equations

$$\begin{aligned} r^I &= \frac{\partial}{\partial t^I} \mathcal{F}_{\text{PNO-CASPT2}} \\ &= \sum_J \langle \Psi^I | F - \langle F \rangle | \Psi_J \rangle t^J - \langle \Psi^I | H | \Psi_0 \rangle \rightarrow 0 \end{aligned} \quad (18)$$

where IJ represent one of the eight non-redundant subspaces of FOIS. The Hylleraas-type energy functional for PNO-CASPT2 ansatz is given as

$$\mathcal{F}_{\text{PNO-CASPT2}} = \langle \Psi | H | \Psi_0 \rangle + \langle \Psi_0 | H | \Psi \rangle + \langle \Psi | F - \langle F \rangle | \Psi \rangle. \quad (19)$$

The amplitudes in the r-ICB representation ($\tilde{\mathbf{t}}$) can be obtained by back-transforming the nr-ICB counterpart (\mathbf{t}) as

$$\tilde{t}_{ij}^{pq} = \sum_{\rho} C_{pq}^{\rho} t_{ij}^{\rho}. \quad (20)$$

In typical canonical CASPT2 implementation, the residua that correspond to Eq. (18) are evaluated in r-ICB representation using the $\tilde{\mathbf{t}}$ amplitudes, and then transformed into the nr-ICB representation as

$$r_{ij}^\rho = \sum_{\rho} C_{\rho q}^\rho \tilde{r}_{ij}^{pq}. \quad (21)$$

for the $\{\Psi_{ij}^\rho\}$ subspace.

In Eq. (15), the PNOs are introduced only in the external subspaces and a semi-internal subspace spanned by $\{\Psi_{ij}^{\rho a_{ij}}\}$ function. Since the PNOs for $\{\Psi_\rho^{a_\rho b_\rho}\}$ and $\{\Psi_{\rho i}^{a_{\rho i} b_{\rho i}}\}$ subspaces are dependent also on the nr-ICBs, in the PNO-CASPT2 implementation, one cannot back-transform the external amplitudes (\mathbf{t}) and the residua (\mathbf{r}) into the r-ICB representation while taking advantage of compactness of the PNO space. Therefore, in our PNO-CASPT2 implementation, we do not perform any back-transformation into the r-ICB representation and the residua are constructed directly in the nr-ICB representation using the orthonormalized amplitudes. Thee explicit formuals for the orthonormalized amplitudes are given in Appendix I.

The PNOs for ij -, ρi - and ρ -pairs are generated by diagonalizing the pair-densities for the corresponding pairs:

$$(D^{ij})_{ab} = \langle \Psi_{ij} | E_b^a | \Psi_{ij} \rangle \quad (\text{for } \{\Psi_{ij}^{ab}\} \text{ subspace}) \quad (22)$$

$$(D^{\rho i})_{ab} = \langle \Psi_{\rho i} | E_b^a | \Psi_{\rho i} \rangle \quad (\text{for } \{\Psi_{\rho i}^{ab}\} \text{ subspace}) \quad (23)$$

$$(D^\rho)_{ab} = \langle \Psi_\rho | E_b^a | \Psi_\rho \rangle \quad (\text{for } \{\Psi_\rho^{ab}\} \text{ subspace}) \quad (24)$$

$$(25)$$

For $\{\Psi_{ij}^{\rho a_{ij}}\}$ subspace, we use the ij -PNOs obtained as eigenfunctions of Eq. (22). Those PNOs with smaller occupation numbers than a user defined threshold are screened out. The PNO truncation error for a pair is estimated by taking difference between full and truncated semi-local (SL-) CASPT2-D pair-energies.

$$e_{ij} = \langle \Psi_0 | H | \Psi_{ij} \rangle \quad (26)$$

$$e_{\rho i} = \langle \Psi_0 | H | \Psi_{\rho i} \rangle \quad (27)$$

$$e_\rho = \langle \Psi_0 | H | \Psi_\rho \rangle \quad (28)$$

$$(29)$$

Moreover, only those pairs with pair-energy larger than a given threshold proceeds to the iterative

PNO-CASPT2/CEPT2 step. The SL-CASPT2-D pair-functions are used for defining the pair-densities

$$|\Psi_{ij}\rangle = \sum_{ab} \frac{(ia|jb)}{F_{ii} + F_{jj} - \epsilon_a - \epsilon_b} E_{ij}^{ab} |\Psi_0\rangle \quad (30)$$

$$|\Psi_{\rho i}\rangle = \sum_{ab} \frac{\langle \Psi_{\rho i}^{ab} | H | \Psi_0 \rangle}{F_{ii} - e_{\rho} - \epsilon_a - \epsilon_b} \sum_p C_p^{\rho} E_{ip}^{ab} |\Psi_0\rangle \quad (31)$$

$$|\Psi_{\rho}\rangle = \sum_{ab} \frac{\langle \Psi_{\rho}^{ab} | H | \Psi_0 \rangle}{e_{\rho} - \epsilon_a - \epsilon_b} \sum_{pq} C_{pq}^{\rho} E_{pq}^{ab} |\Psi_0\rangle. \quad (32)$$

The numerators in the SL-CASPT2-D amplitudes involve 2-external two-electron integrals and hence this part will be a computational bottleneck in a whole PNO-CASPT2 computation. In our current implementation, we generate a full set of canonical 2-external integrals using the resolution-of-the-identity (RI) approximation and store them on disk. This choice limits the applicability of our PNO-CASPT2 only up to systems composed of not more than 2,000 AO functions. To overcome such a difficulty, domain truncation should be introduced in the RI 3-index integral generation and the final 2-external integral construction steps as done in the original PNO-CASPT2 implementations,^{38,39} in the DLPNO-CC and NEVPT2 algorithms by Neese and coworkers^{54–59,63,98} and in the PNO-LCC programs by Werner *et al.*^{64–66,99}

In the canonical CASPT2 implementation, the nr-ICBs are constructed as eigenfunctions of diagonal blocks of the zeroth-order Hamiltonian by solving the generalized eigenvalue problems akin to Eq. (17) for all the eight subspaces. Therefore, programming the residua (Eq. 18) of diagonal blocks in the first term is quite simple. However, in the PNO-based counterpart, all the matrix blocks involving at least one DOMO index should be programmed, leading to a drastic increase in the number of terms that should be derived and programmed. To this end, we extended our code generator framework^{90,91,100} such that codes for the PNO-based tensor contractions can also be generated. In our program, the PNO-CASPT2 residu equations are solved by the preconditioned conjugate gradient (PCG) algorithm.

We have also implemented real and imaginary shifts in our PNO-CASPT2 program in the same way as the canonical CASPT2 program. The conventional formulation of the imaginary shifts is based on the diagonality in the diagonal blocks of zeroth-order Hamiltonian matrix in FOIS which is not satisfied if the DOMOs are localized. Therefore, in our PNO-CASPT2 implementatin, the off-diagonal elements in the diagonal blocks are discarded, leading to a semi-canonical imaginary shift.

C. The Coupled-Electron Pair Perturbation Theory

In the PNO-CEPT2 ansatz, we minimize the following energy functional

$$\mathcal{F}_{\text{PNO-CEPT2}} = \mathcal{F}_{\text{PNO-CEPA/0}}^{\text{ext}} + \mathcal{F}_{\text{PNO-CASPT2}} - \mathcal{F}_{\text{PNO-CASPT2}}^{\text{ext}} \quad (33)$$

$$\mathcal{F}_{\text{PNO-CEPA/0}}^{\text{ext}} = \langle \Psi^{\text{ext}} | H - E_0 | \Psi^{\text{ext}} \rangle \quad (34)$$

$$\mathcal{F}_{\text{PNO-CASPT2}}^{\text{ext}} = \langle \bar{\Psi}^{\text{ext}} | H | \Psi_0 \rangle + \langle \Psi_0 | H | \bar{\Psi}^{\text{ext}} \rangle + \langle \bar{\Psi}^{\text{ext}} | F - \langle F \rangle | \bar{\Psi}^{\text{ext}} \rangle \quad (35)$$

where $\bar{\Psi}^{\text{ext}}$ represents the external part of the wave function

$$\begin{aligned} |\Psi^{\text{ext}}\rangle &= |\Psi_0\rangle + |\bar{\Psi}^{\text{ext}}\rangle \\ &= |\Psi_0\rangle + \left[\sum_{ij} \sum_{a_{ij}b_{ij}} t_{a_{ij}b_{ij}}^{ij} |\Psi_{ij}^{a_{ij}b_{ij}}\rangle \right. \\ &\quad \left. + \sum_{\rho i} \sum_{a_{\rho i}b_{\rho i}} t_{a_{\rho i}b_{\rho i}}^{\rho i} |\Psi_{\rho i}^{a_{\rho i}b_{\rho i}}\rangle + \sum_{\rho} \sum_{a_{\rho}b_{\rho}} t_{a_{\rho}b_{\rho}}^{\rho} |\Psi_{\rho}^{a_{\rho}b_{\rho}}\rangle \right]. \end{aligned} \quad (36)$$

By differentiating the above functional with respect to the amplitudes, one obtains the PNO-CEPT2 residual equations as

$$r^E = \langle \Psi^E | H | \Psi_0 \rangle + \sum_{E'} \langle \Psi_E | H - E_0 | \Psi_{E'} \rangle t^{E'} + \sum_A \langle \Psi_E | F | \Psi_A \rangle t^A \rightarrow 0 \quad (37)$$

$$r^A = \langle \Psi^A | H | \Psi_0 \rangle + \sum_E \langle \Psi_A | H | \Psi_E \rangle t^E + \sum_{A'} \langle \Psi_A | F - \langle F \rangle | \Psi_{A'} \rangle t^{A'} \rightarrow 0 \quad (38)$$

where $\{E\}$ and $\{A\}$ represent the external and the remaining subspaces in FOIS, respectively. If one evaluates the diagonal block for $\{\Psi_{\rho}^{a_{\rho}b_{\rho}}\}$ straightforwardly using Wick's theorem, there are two terms involving 4-body RDM whose size is approximately 32 gigabyte for systems composed of 16 active MOs. To eliminate such expensive contractions, we employ a commutator-based transformation originally proposed by Angeli and coworkers²⁵⁻²⁷

$$\begin{aligned} r_{a_{\rho}b_{\rho}}^{\rho} &= \sum_{\tau} \sum_{c_{\tau}d_{\tau}} \langle \Psi_{a_{\rho}b_{\rho}}^{\rho} | H - E_0 | \Psi_{\tau}^{c_{\tau}d_{\tau}} \rangle t_{c_{\tau}d_{\tau}}^{\tau} \\ &= \sum_{\tau} \sum_{c_{\tau}d_{\tau}} \sum_{pqrs} C_{pq}^{\rho} \langle \Psi_0 | E_{a_{\rho}b_{\rho}}^{pq} (H - E_0) E_{pq}^{c_{\tau}d_{\tau}} | \Psi_0 \rangle C_{rs}^{\tau} t_{c_{\tau}d_{\tau}}^{\tau} \\ &= \sum_{\tau} \sum_{c_{\tau}d_{\tau}} \sum_{pqrs} C_{pq}^{\rho} \langle \Psi_0 | E_{a_{\rho}b_{\rho}}^{pq} [H, E_{pq}^{c_{\tau}d_{\tau}}] | \Psi_0 \rangle C_{rs}^{\tau} t_{c_{\tau}d_{\tau}}^{\tau} \end{aligned} \quad (39)$$

as we have also utilized in our previous works for developing an approximated FIC-MRCI variants with a DMRG reference function.^{90,91} Note that both the CEPT2 and the CIPT2⁸⁰ methods use the

energy functional of the similar form. The only difference between them consists in the choice of the CEPA subspaces; in the CEPT2 ansatz the external configurations are treated at the CEPA level while in the CIPT2 method the CEPA functional is used for in subspaces with three active MO indices i.e., $\{\Psi_i^o\}$ and $\{\Psi_\rho^a\}$.

The second term in Eq. (37) involves contractions of the 4-external exchange-type integrals with the 2-external amplitudes which is known as the most expensive terms in the canonical CC or CEPA implementations. However, such terms are typically not a bottleneck any more if the virtual space is spanned by the PNOs. Some of the PNO-CEPA terms involve the semi-joint pair-pair interactions and in the MR case these terms appear to be more involved. Apparently, in the single-reference limit, the PNO-CEPT2 energy and wave function converge to those of PNO-CEPA/0 with Doubles (PNO-CEPA/0(D)) or equivalently PNO-Linearized Coupled-Cluster Doubles (PNO-LCCD) wave function.

All the CEPA terms in Eq. (37) are *linked* in the sense that the amplitude is either directly or indirectly via 1-body density cumulant connected to the integral. Therefore, as addressed in Ref. 101, even for a super system ($A \cdots B$) composed of infinitely separated two subsystems (A and B), no *unlinked* contractions appear. This indicates that the CEPT2 extension does not violate the near-size-consistent character of original CASPT2 model.

Unlike CIPT2 which is designed to mitigate the intruder state problems typically stemming from the $\{\Psi_i^o\}$, $\{\Psi_\rho^a\}$ and the reference subspaces, in CEPT2, we use the CASPT2 ansatz for those subspaces. In the single-reference case, it is known that the CEPA/0 energy can be irregular thus showing discontinuity in the potential energy surface. To remedy this drawback, Taube introduced a regularization scheme which is closely related to the imaginary shift in the CASPT2 framework.¹⁰² Therefore, we have implemented the real- and semi-canonical imaginary shifts and the Hylleraas corrections to minimize the errors caused by such shifts.

Our current implementation of the PNO-CEPT2 is still not of optimal form since only the 4-external terms and the 1-body terms such as those similar to the contractions from $\mathcal{F}_{\text{PNO-CASPT2}}^{\text{ext}}$ are fully evaluated in the PNO space. All the remaining terms from $\mathcal{F}_{\text{PNO-CEPA/0}}^{\text{ext}}$, which involve either 4-internal integral or 2-external integral of semi-joint pair-pair interaction type,^{49,50} are constructed in the canonical space using the back-transformed \mathbf{t} amplitudes into the canonical space. Therefore, we only demonstrate and benchmark the accuracy of the PNO-CEPT2 model for small- to medium-size molecules and the benchmarking the efficiency is beyond the scope of this manuscript.

D. PNO-based Code Generation

The automatic derivation and code generation technique has been a quite powerful strategy for developing and testing the novel wave function methods which often involve hundreds or thousands of tensor contraction terms to implement.^{85,92,93,101,103–122} To generate an efficient contraction code, each of the tensor contraction terms should be divided into a stream of binary contractions. This is also the case for the code generations employing the PNOs spanning the virtual space. Even though the global optimization scheme proposed by Hanrath and Engels-Putzka for developing the efficient higher-order CC codes^{123,124} can also be used in such a context, in order to keep the generator tool relatively simple yet effective, we use a more heuristic strategy for forming the optimal binary contractions.

In canonical MO basis, typical contraction terms in the CEPT2 model read

$$\begin{aligned}
r_{ab}^{\rho} \leftarrow & \frac{1}{4} \sum_{\tau} \sum_{pqrs} \sum_c (f_{\text{core}})_{ca} D_{rs}^{pq} t_{cb}^{\tau} C_{sr}^{\tau} C_{pq}^{\rho} \\
& - \frac{1}{4} \sum_{\tau} \sum_{pqrst} (f_{\text{core}})_{ts} D_{rs}^{pq} t_{ba}^{\tau} C_{pq}^{\tau} C_{tr}^{\rho} \\
& + \frac{1}{4} \sum_{\tau} \sum_{pqrstu} \sum_c (uc|qa) D_{stu}^{pqr} t_{cb}^{\tau} C_{st}^{\rho} C_{pr}^{\tau} \\
& + \frac{1}{4} \sum_{\tau} \sum_{pqrstuv} (ur|tv) D_{stu}^{pqr} t_{ba}^{\tau} C_{pq}^{\rho} C_{vs}^{\tau} \\
& - \frac{1}{4} \sum_{\tau} \sum_{pqrst} (st|ru) D_{rs}^{pq} t_{ba}^{\tau} C_{qp}^{\rho} C_{ut}^{\tau} \\
& + \frac{1}{4} \sum_{\tau} \sum_{pqrs} \sum_{cd} (ac|bd) D_{rs}^{pq} t_{cd}^{\tau} C_{sr}^{\rho} C_{qp}^{\tau} \\
& + (18 \text{ more terms obtained by permuting pairs of indices})
\end{aligned} \tag{40}$$

for the $\{\Psi_{\rho}^{ab}\}$ subspace. Even though each term of Eq. (40) is composed of five tensor quantities resulting in XXX ways to form binary contractions, we find that the RDM is always contracted with two orthonormalization matrices (**C**). Moreover, if the MO integral involves at least one active MO indices, it is also contracted either with an RDM or with one **C** matrix. Therefore, after forming such amplitude-independent intermediates, Eq (40) becomes

$$\begin{aligned}
r_{ab}^{\rho} \leftarrow & \frac{1}{4} \sum_{\tau} \sum_c (f_{\text{core}})_{ca} (W_0)_{\rho\tau} t_{cb}^{\tau} - \frac{1}{4} \sum_{\tau} (f W_1)_{\rho\tau} t_{ba}^{\tau} + \frac{1}{4} \sum_{\tau} \sum_c (v W_2)_{\rho\tau, ca} t_{cb}^{\tau} \\
& + \frac{1}{4} \sum_{\tau} (W_3)_{\rho\tau} t_{ba}^{\tau} - \frac{1}{4} \sum_{\tau} \sum_c (W_4)_{\rho\tau} t_{ba}^{\tau} + \frac{1}{4} \sum_{\tau} \sum_{cd} (ac|bd) (W_5)_{\rho\tau} t_{cd}^{\tau}
\end{aligned}$$

$$+ (18 \text{ more terms obtained by permuting pairs of indices}). \quad (41)$$

By comparing the indices of the amplitudes, the generator can form an additional intermediate

$$(xW_6)_{\rho\tau} = (fW_1)_{\rho\tau} + (W_4)_{\rho\tau} \quad (42)$$

and the number of amplitude-dependent contractions are further reduced. In our current PNO-CASPT2/CEPT2 implementation, all the amplitude independent-intermediates such as (W_n) , (fW_n) , (vW_n) and (xW_n) are constructed in canonical MO basis and stored in fast core-memory before proceeding to the PCG iterations for solving the amplitude equations in PNO space. The amplitude-independent intermediates are further subdivided into a stream of binary contractions and constructed using DGEMM subroutine assuming all the tensor quantities are stored in fast core-memory.

The CEPT2 residua (Eq. 41) with an additional intermediate (Eq. 42) are then transformed into PNO-based computer code assuming only the amplitudes and the residua are the native-PNO quantities. At each step of the PCG iteration, the amplitude-dependent intermediates involving a Fock matrix are constructed such as

$$(fvvt)_{a_\rho b_\rho}^\rho = \sum_{c_\rho} (f_{\text{core}})_{a_\rho c_\rho} t_{c_\rho b_\rho}^\rho \quad (43)$$

$$(tfcc)_{a_{\rho i} b_{\rho i}}^\rho = \sum_k \sum_{a_{\rho k} b_{\rho k}} (f_{\text{core}})_{ik} S_{a_{\rho i} a_{\rho k}} t_{c_{\rho k} b_{\rho k}}^{\rho k} S_{b_{\rho k} b_{\rho i}} \quad (44)$$

where \mathbf{S} represent the pair-pair overlap matrices which are all stored on disk. As in case of Eq. (41), if the pair indices of the amplitudes and the residuum, which are τ and ρ , respectively, are different, the generator call a subroutine for projecting the amplitude from the τ -PNOs space to the ρ -PNO space. By this procedure, all the PNO-based tensor contractions which do not involve any two-electron integrals in Eq. (41) are transformed into

$$\begin{aligned} r_{a_\rho b_\rho}^\rho \leftarrow & \frac{1}{4} \sum_{\tau} (W_0)_{\rho\tau} \left[\sum_{a_\tau b_\tau} S_{a_\rho a_\tau} (fvvt)_{a_\tau b_\tau}^\tau S_{b_\tau b_\rho} \right] - \frac{1}{4} \sum_{\tau} (xW_6)_{\rho\tau} \left[\sum_{a_\tau b_\tau} S_{b_\rho b_\tau} t_{b_\tau a_\tau}^\tau S_{a_\tau a_\rho} \right] \\ & + \frac{1}{4} \sum_{\tau} (W_3)_{\rho\tau} \left[\sum_{a_\tau b_\tau} S_{b_\rho b_\tau} t_{b_\tau a_\tau}^\tau S_{a_\tau a_\rho} \right] \end{aligned} \quad (45)$$

and are constructed efficiently using DGEMM for projecting the PNOs from τ -pair to ρ -pair and DAXPY for summing up each contribution into the residua.

All the 4-external terms that appear in PNO-CEPT2 such as the sixth term in Eq. (41) have the similar structure

$$r_{a_\rho b_\rho}^o \leftarrow \frac{1}{4} \sum_{c_\rho d_\rho} (a_\rho c_\rho | b_\rho d_\rho) \left[\sum_{\tau} (W_5)_{\rho\tau} \left[\sum_{c_\tau d_\tau} S_{a_\rho a_\tau} t_{c_\tau d_\tau}^\tau S_{b_\tau b_\rho} \right] \right] \quad (46)$$

$$r_{a_{\rho i} b_{\rho i}}^{oi} \leftarrow 2 \sum_{c_{\rho i} d_{\rho i}} (a_{\rho i} c_{\rho i} | b_{\rho i} d_{\rho i}) \left[\sum_{\tau} (W_{124})_{\rho\tau} \left[\sum_{c_{\tau i} d_{\tau i}} S_{a_{\rho i} a_{\tau i}} t_{c_{\tau i} d_{\tau i}}^{\tau i} S_{b_{\tau i} b_{\rho i}} \right] \right] \quad (47)$$

and so we have written an optimized subroutine for efficiently calculate those terms in the PNO basis which are called by the generator.

For those subspaces which do not involve any PNOs and the coupling matrix elements of the canonical and the PNO subspaces, the PNO-based amplitudes are back-transformed into the canonical space and used to form the similar contractions.

III. RESULTS AND DISCUSSION

A. Non-Parallelity Errors for N₂ Dissociation

To assess the performance of canonical CEPT2 model and the validity of the PNO truncation, we calculated the dissociation curve of N₂ molecule in the singlet state using canonical CASPT2 and CEPT2 models. The results are compared with those obtained by Davidson-corrected Multireference Configuration Interaction (MRCI+Q) and the size-consistency-corrected variants such as Averaged-Coupled-Pair Functional (ACPF), and MR-CEPA/0. In all the CASPT2 and CEPT2 computations, no IPEA and level shifts were used. Errors from the MRCI+Q values are shown in Fig. II. The non-parallelity errors (NPEs) are given in Table I. Orca 4.2 program package⁵³ was used for FIC-NEVPT2,²⁶ FIC-MRCI,⁹³ FIC-CEPA/0 and FIC-ACPF¹²⁵ computations. In Table I, NPE by the CEPT2 model is shown to be smaller than that of the CASPT2 by about 3.8 kcal/mol. Even though amounts of the dynamical correlation energies recovered by NEVPT2 model are smaller than those by CASPT2 by more than 15 kcal/mol, the NPE in the NEVPT2 energies is smaller than those by CASPT2 and CEPT2 models.

In Table II, the dynamical correlation energies recovered by PNO-CEPT2 model are shown for N₂ molecule with various internuclear distances. To obtain approximately 99.9 % of the correlation energy, the PNO truncation threshold, which is coined TCutPNO, should be tightened by up to 1.0×10^{-8} . Surprisingly, the correlation energy recovered appears to be smallest at 1.0 Å which is

close to the equilibrium internuclear distance. On the other hand, in the strongly-correlated region where the triple bond is being broken, the PNO approximation performs relatively well recovering approximately 99.9 % of the canonical correlation energy even with $\text{TCutPNO} = 5.0 \times 10^{-8}$.

B. Isomerization of $[\text{Cu}_2\text{O}_2]^{2+}(\text{NH}_3)_6$

We applied the PNO-CEPT2 model to isomerization of $[\text{Cu}_2\text{O}_2]^{2+}(\text{NH}_3)_6$ complex from the bis(μ -oxo) to the $\mu - \eta^2 : \eta^2$ -peroxo structures, which is a typical benchmark system for MR methods.^{101,126,127} The O_2 activation mechanism in enzymes such as hemocyanin is known to be mediated by interconversion of $[\text{Cu}_2(\mu - \eta^2 : \eta^2\text{-peroxo})]^{+2}$ and $[\text{Cu}_2(\mu\text{-oxo})]^{+2}$ cores. To accurately determine the isomerization pathways, numerous attempts have been made employing $[\text{Cu}_2\text{O}_2]^{2+}(\text{NH}_3)_6$ complex as an active-site model for O_2 activation reactions.

A particular difficulty of the isomerization of this complex consists in the fact that the CASPT2 and MRCI+Q results strongly disagree with each other: With CAS(8e, 10o), the CASPT2 predicts that the bis(μ -oxo) structure is lower in the energy while using the MRCI+Q and MR-ACPF models $\mu - \eta^2 : \eta^2$ -peroxo structure appears to be more stable. Recently, Köhn and co-workers¹⁰¹ have performed a set of benchmark calculations on this system using IC-MR Coupled-Cluster (IC-MRCC)^{111,128} and the higher-order MRPT methods and found that all the higher-order methods than the second-order of perturbation expansion predicts that the $\mu - \eta^2 : \eta^2$ -peroxo structure is lower in the energy. This is actually consistent with the IC-MRCI+Q calculations published by Rode and Werner in 2005.¹²⁶ To produce the consistent energy ordering to the IC-MRCI+Q and IC-MRCC calculations using CASPT2-type wave function, one has to employ a larger active space involving all the 3d and the double-shell 4d orbitals of copper atoms thus leading to active space composed of 24 electrons in 28 orbitals as reported in RAS(24e, 28o)PT2 study by Gagliardi and co-workers¹⁰ and cumulant-based DMRG-CASPT2 study by Yanai and co-workers¹²⁷ Therefore, it is interesting to see how much improvement over the PNO-CASPT2 is obtained by the PNO-CEPT2 model while keeping the active space CAS(8e, 10o).

Isomerization energy profiles calculated by PNO-CASPT2/CEPT2 methods are shown in Fig. 2 as a function of Cu-Cu distance. The bis(μ -oxo) and $\mu - \eta^2 : \eta^2$ -peroxo structures were taken from Ref. 85 and all the intermediates geometries were generated as a superposition of two isomeric geometries. The isomerization energies ($E(\mu - \eta^2 : \eta^2\text{-peroxo}) - E(\text{bis}(\mu\text{-oxo}))$) calculated at CASSCF, PNO-CASPT2 and PNO-CEPT2 are -27.5 kcal/mol, +11.4 kcal/mol and +9.6 kcal/mol,

respectively as can be seen in Table III. Difference between the previous CASPT2(8e, 10o) results by Rode *et al.* and our PNO-CASPT2(8e, 10o) calculations with larger quadruple ζ basis sets is stemming from the difference in the basis sets, and PNO and weak-pair truncation errors. Still, the difference reaches only up to about 1.2 kcal/mol and is quite small in comparison with discrepancy between the MRCI+Q(8e, 10o) and the CASPT2(8e, 10o) results. The PNO-CEPA extension in the PNO-CEPT2 model corrects the PNO-CASPT2 results in the direction of MRCI+Q(8e, 10o) result by up to about 1.8 kcal/mol. In Table IV, the magnitude of the PNO-CEPT2 corrections to each subspace is analyzed. As can be seen, the CEPA extension to $(c,c) \rightarrow (v,v)$ subspace corrects the dynamical correlation energy by about up to -21.0 kcal/mol for both bis(μ -oxo) and $\mu - \eta^2 : \eta^2$ -peroxo states thus resulting in almost perfect cancellation in the isomerization energy. The 2-external subspaces with at least one active MO indices give rise to larger change in the isomerization energy by up to However, the isomerization energy profile calculated by PNO-CEPT2 model is still similar to that by PNO-CASPT2 and the isomerization energy still appears to be far off from the IC-MRCI+Q and the IC-MRCC values. Therefore, at least in this case, the CEPA extension in the 2-external subspaces gives only a minor correction to the CASPT2 isomerization energy.

C. Ground and Excited States of Butadiene and Linear Polyenes

Predicting low-lying dark ($2^1A_g^-$) and bright ($1^1B_u^+$) excited states of butadiene has been known as notoriously challenging despite as reported in Ref. 129. To achieve qualitative accuracy in calculating the EE for the accessible $1^1B_u^+$ state, inclusion of the dynamic correlation plays a key role. On the other hand, the dipole-forbidden $2^1A_g^-$ state is dominated by doubly-excited character and is of strong multireference nature even though there is no reliable experimental EEs reported for this state. Therefore, the typical single-reference excited state methods such as Equation-Of-Motion Coupled-Cluster with Singles and Doubles (EOM-CCSD) are not the appropriate choices for the $2^1A_g^-$ state even though there is no reliable experimental EE for this state.

In Table V, EEs for the $1^1B_u^+$ and $2^1A_g^-$ states calculated by canonical CASPT2 and CEPT2 models are shown in comparison with various theoretical and experimental values. Geometries for butadiene and longer polyene chains were taken from Ref. 127. In Ref. 129, Watson *et al.* have proposed the best theoretical EEs by using EOM-CC method including up to quadruple excitations (EOM-CCSDTQ). It is seen that the CC2, EOM-CCSD and EOM-CCSD(T) values largely deviate

from the EOM-CCSDTQ values for the $2^1A_g^-$ state that possesses doubly-excited character while giving reasonably well agreement for $1^1B_u^+$. To obtain good agreement with the EOM-CCSDTQ results for both states in a single-reference framework, at least, CC3 level of theory should be used. The CASSCF values which lacks dynamic correlation effects show large deviation by up to 2.3 eV from the EOM-CCSDTQ result for $1^1B_u^+$. Addition of the dynamic correlation correction on top of the CASSCF energies significantly remedy the CASSCF results and the CASPT2 gives reasonably well agreement with the EOM-CCSDTQ values while in the CASPT2 results in Ref. 130 $1^1B_u^+$ and $2^1A_g^-$ are predicted to be almost degenerated. The EEs calculated by CEPT2 model are quite close to those by MR-AQCC results and in good agreement with the EOM-CCSDTQ results.

The $1^1B_u^+$ and $2^1A_g^-$ states of longer polyene chains were used as a benchmark sets for the cumulant-approximated CASPT2¹²⁷ and NEVPT2¹³¹ studies to assess the errors caused by the cumulant approximations in the 3- and 4-RDMs. In this study, we do not utilize the cumulant approximations in the RDMs. However, to assess the impact of CEPA/0 extensions in the PNO-CEPT2 model on the EEs, we calculated the vertical EEs for $1^1B_u^+$ and $2^1A_g^-$ states of conjugated linear polyene molecules ($C_{2n}H_{2n+2}$) using CAS(2n e , 2n o). In Fig. 3, the EEs calculated at the canonical CASPT2 and PNO-CEPT2 level and the difference in the EEs are shown. Interestingly, in both CASPT2 and PNO-CEPT2 results, the $1^1B_u^+$ state appears to be lower for C_2H_4 in accordance with previous results¹²⁷ while for C_2H_4 and the longer chains the order is switched. As can be seen from Fig. 3 c), the EEs calculated by the PNO-CEPT2 model are always higher than those by the CASPT2. However, for C_4H_4 the PNO-CEPA correction works more strongly on the $2^1A_g^-$ state while for the other polyene molecules, the PNO-CEPA correction on the $1^1B_u^+$ state is larger than the that on the other by up to about 0.1 eV for C_8H_{10} .

D. Singlet-Triplet Gap of Free-base Porphyrin

We calculated the non-vertical singlet-triplet (S–T) energy gaps for free-base porphyrin molecule. The geometries for S_0 and T_0 states of free-base porphyrin were taken from Ref. 90. In Table VI, the S–T gaps and the dynamic correlation energies recovered by various PNO cutoff thresholds are shown. It is seen that the PNO-CASPT2 model shows good agreement with the experimental value for all the PNO truncation thresholds even for quite loose threshold such as 1.0×10^{-6} , thus indicating that the error cancellation works surprisingly fine for this systems. This is most probably due to the fact that the S_0 and T_0 geometries are similar enough to each other. The

PNO-CEPT2 model gives even closer values to the experimental one. The compression ratios of the first-order amplitudes, which are calculated as a ratio between total number of amplitudes in Eq. (15) and the canonical counterpart, are also shown. Even with the tightest threshold used, 1.0×10^{-9} , the PNO-CASPT2/CEPT2 models require only less than 6 % of the amplitudes while giving quite good agreement with the untruncated value. The PNO-CEPT2 values agree well also to the cumulant-approximated MRCI+Q and ACPF results that use the DMRG-CASSCF reference function with full-valence π active space. Note that none of computational values in Table VI include the solvent-effects.

IV. CONCLUSION

To obtain qualitative accuracy in predicting the reaction energies and various chemical energetics, a balanced treatment between static and dynamic electron correlation effects plays a key role. One of the most commonly used methods is the MR second-order perturbation theory such as CASPT2 and NEVPT2, both of which converge to the MP2 method in the closed-shell SR limit. As a simple yet higher order extension to the CASPT2 method, we have developed a hybrid of MR-CEPA/0 and CASPT2 Ansätze that converges to the CEPA/0(D) in the closed-shell SR limit, which is coined CEPT2 Ansatz. One of the largest bottleneck of the CEPT2 computation that is stemming from the MR-CEPA/0 terms in the residual equations is the presence of the so-called 4-EEOs involving a contraction of the 4-external two-electron integrals and the amplitude. To accelerate the CEPT2 computation, the CEPT2 equations are expanded in the local PNO basis which a compact set of virtual orbitals specifically optimized to each pair of localized orbitals and the nr-ICBs. Development of the PNO-CEPT2 computer programs was conducted using the automatic code generation technique and interfaced to our in-house quantum chemistry program package.

For N_2 dissociation, the CEPT2 model was shown to give a smaller NPE than that of CASPT2 model in comparison with the reference FIC-MRCI+Q results. The errors caused by the PNO truncation were examined and shown to be the largest at around the equilibrium internuclear distance.

The PNO-CEPT2 model was applied to calculating the isomerization energy profiles of $[Cu_2O_2]^{2+}(NH_3)_6$ complex from the bis(μ -oxo) to the $\mu - \eta^2 : \eta^2$ -peroxo structures. The PNO-CEPT2 results show a similar trend to the CASPT2 as long as CAS(8e, 10o) is used and strongly disagree with the previous IC-MRCI+Q and IC-MRCC results. To remedy the accuracy of the

PNO-CEPT2 model, the higher-order treatment of the subspaces with three active MO indices (E_{qr}^{ip} and E_{pq}^{ra}) will be necessary. However, simple use of the IC-MR-CEPA ansatz into those subspaces introduce a complicated tensor contraction involving the 4-RDMs and the amplitude and the PNOs cannot accelerate construction of such terms. Another possibility to improve the accuracy of the PNO-CEPT2 model is to use unconventionally large active space using the DMRG reference function. As all the terms involving the 4-RDMs are not more complicated than those in the CASPT2 mode, combination of the PNO-CEPT2 model and the DMRG reference function via use of the cumulant-approximated 4-RDM is quite straightforward. Nevertheless, previous studies have shown that simple use of cumulant-approximated RDM often introduces unavoidable instability in the residual equation. Therefore, as a future development, we prefer to pursue other possibilities such as uncontracting the E_{qr}^{ip} and E_{pq}^{ra} subspaces using the Matrix-Product State (MPS) basis.

The CEPT2 was shown to give good agreement with the EOM-CCSDTQ results on calculating the excitation energies of butadiene achieving a good balance between dynamic and static electron correlations. For longer polyene systems, the PNO-CEPT2 produces the larger EEs than those by the CASPT2 model by up to 0.29 eV.

For calculating the non-vertical S–T gap of free-base porphyrin where the relaxation of the geometry in the triplet state is relatively small, the PNO and weak-pair truncations work surprisingly fine thus producing a S–T gap in a good agreement with the experimental value. Size of the PNO-CEPT2 amplitude is only up to less than 6 % of the canonical counterpart even with the PNO and the weak-pair truncation thresholds are set to 1.0×10^{-9} and 1.0×10^{-5} Eh, respectively.

We find that the IC-MR-CEPA extension to the CASPT2 model in the 2-external subspaces leads to the improvement in the accuracy. However, the PNO-CEPT2 model is not always accurate enough especially if the active space is too small. To improve the accuracy while keeping the active space as small as possible, higher order extension to E_{qr}^{ip} and E_{pq}^{ra} subspaces will be important. A production level implementation of the PNO-CEPT2 model is currently in progress.

TABLE I: The NPEs in kcal/mol for N_2 dissociation by various FIC methods with respect to the FIC-MRCI+Q energies.

	CASPT2	CEPT2	FIC-NEVPT2	FIC-MRCI	FIC-CEPA/0	FIC-ACPF
NPEs / kcal/mol	9.98	6.21	2.99	2.03	0.98	0.68

TABLE III: Isomerization energies calculated by size-extensive version of the completely-renormalized CCSD with perturbative triples (CR-CCSD(T)_L) and various MR methods. For the PNO-CASPT2/CEPT2 calculations, the PNO and weak-pair truncation thresholds were set to 5.0×10^{-8} and 1.0×10^{-5} Eh, respectively and the relativistic effects were not included.

Method	$E(\mu - \eta^2 : \eta^2\text{-peroxo}) - E(\text{bis}(\mu\text{-oxo}))$ / kcal/mol
CR-CCSD(T) _L ^{a,b}	-10.1
FIC-MRCCSD(8e,10o) ^{a,b}	-9.4
IC-MRCI+Q(8e,10o) ^{a,b}	-12.4
DMRG-cu(4)-CASPT2(24e, 28o) ^c	-4.9
DMRG-CASSCF(24e, 28o) ^c	-21.3
RASPT2(24e,28o) ^{b,d}	-7.6
CASSCF(16e,14o) ^{a,b}	-29.8
CASPT2(16e,14o) ^{a,b}	+17.2
CASSCF(8e,10o) ^{b,e}	-23.4
CASPT2(8e,10o) ^{b,e}	+10.2
IC-MRCI+Q(8e,10o) ^{b,e}	-11.6
PNO-CASPT2(8e,10o) (This work)	+11.4
PNO-CEPT2(8e,10o) (This work)	+9.6

^a Taken from Ref. [101](#)

^b Relativistic effects were included by the effective core potentials (ECPs) on copper atoms

^c Taken from Ref. [127](#)

^d Taken from Ref. [10](#)

^d Taken from Ref. [126](#)

TABLE II: Dynamic correlation energies recovered (%) by PNO-CEPT2 model for N₂ with various PNO truncation thresholds with def2-QZVPP basis set. No pair-energy-based screening of weak-pairs were performed. 1s orbitals of nitrogen atoms were kept frozen while the 2p orbitals were included in the active space (CAS(6e, 6o)).

R (N-N) / Å	TCutPNO														
	1.0×10^{-11}	1.0×10^{-10}	1.0×10^{-9}	5.0×10^{-9}	1.0×10^{-8}	5.0×10^{-8}	1.0×10^{-7}	5.0×10^{-7}	1.0×10^{-6}	5.0×10^{-6}	1.0×10^{-5}	1.0×10^{-4}

TABLE V: Computed EEs for $1^1B_u^+$ and $2^1A_g^-$ states at canonical CASPT2 and CEPT2 model in comparison with various theoretical and experimental data. The def2-TZVPP basis and def2-TZVPP/JK auxiliary basis sets were used. The C(1s) orbitals were frozen during CASPT2 and CEPT2 computations while all the C(2p_z) orbitals were included in the active space leading to CAS(4e, 4o) treatment. No shifts were used in the zeroth-order Hamiltonian.

FIG. 1. Deviations of canonical CEPT2 energy from those of MRCI+Q for N_2 with various internuclear distances with def2-QZVPP basis set. $1s$ orbitals of nitrogen atoms were kept frozen while all the other orbitals were correlated. All the $2p$ orbitals were included in the active space leading to CAS(6e, 6o) treatment.

TABLE VI: Dynamic electron correlation energies and S–T gaps for free-base porphyrin calculated at PNO-CASPT2/CEPT2 level with various PNO cutoff thresholds in comparison with experimental S–T gap. The def2-SVP basis set was used. The threshold for weak-pair screening was set to 1×10^{-5} Eh. All the $1s$ orbitals of carbon atoms were kept frozen. 8π MOs composed of $2p_z$ orbitals of carbon atoms were included in the active space thus leading to CAS(8e, 8o) settings which is consistent with CAS treatment of Ref. 137. Ratios between total number of PNO-CASPT2/CEPT2 amplitudes to optimize and that of canonical CASPT2, both of which include internal and semi-internal amplitudes, are also shown. Total number of AO basis functions is 406.

TCutPNO	Total Energy (S_0) / Eh	Correlation Energy / Eh	Accuracy (%)	Compression Ratio (%)	Total Energy (T_0) / Eh	Correlation Energy / Eh	Accuracy (%)	Compression Ratio (%)	S–T gap / eV

FIG. 2. Isomerization curves of $[\text{Cu}_2\text{O}_2]^{+2}(\text{NH}_3)_6$ calculated by PNO-CASPT2 and PNO-CEPT2 using def2-QZVPP (O, Mn) and def2-TZVPP (H, N) basis sets. For the RI treatment, def2-TZVPP/C auxiliary basis was used. All the $\text{O}(1s)$, $\text{N}(1s)$, $\text{Fe}(1s, 2s, 2p)$ orbitals were kept frozen at the PNO-CASPT2/CEPT2 steps. The active space is composed of $\text{O}(2p_x, 2p_y, 3p_x, 3p_y)$ and $\text{Fe}(3d_{xy})$ thus leading to $\text{CAS}(8e, 10o)$ treatment. The PNO and weak-pair truncation thresholds were set to 5×10^{-1} and 1×10^{-5} Eh, respectively. Total number of AO basis functions is 752.

FIG. 3. Vertical EEs for linear polyene, $C_{2n}H_{2n+2}$, calculated by a) canonical CASPT2 and the b) PNO-CEPT2 methods using PNO and weak-pair truncation thresholds set to 5.0×10^{-8} and 1.0×10^{-5} Eh, respectively. Figure c) represents difference between canonical CASPT2 and PNO-CEPT2 EEs, $EE(PNO-CEPT2)-EE(CASPT2)$, while Figure d) showing the general chemical formula for polyene chains. The def2-TZVPP basis and def2-TZVPP/JK auxiliary basis sets were used. All the $C(1s)$ orbitals were kept frozen after the reference CASSCF calculation while $C(2p_z)$ orbitals were included in the active space, thus leading to $CAS(2n\ e, 2n\ o)$ treatment. No shifts were used in the zeroth-order Hamiltonian.
